изданий, рекомендованных к публикации
основных научных результатов
диссертаций по медицинским наукам с 27
сентября 2024 года Высшей
аттестационной комиссией Республики
Узбекистан (письмо № 361/6 от 2024
года).

РЕДАКЦИОННАЯ КОЛЛЕГИЯ:

Хайдаров Нодиржон Кадинович – доктор медицинских наук, профессор, ректор Ташкентский государственный медицинский университет. (Узбекистан).

Нуралиев Неккадам Абдуллаевич - доктор медицинских наук, профессор, иммунолог, микробиолог, проректор по научной работе и инновациям Бухарского государственного медицинского института. (Узбекистан).

Кариев Гайрат Маратович – доктор медицинских наук, профессор, директор Республиканского научного центра нейрохирургии Узбекистана. (Узбекистан).

Федин Анатолий Иванович - доктор медицинских наук, профессор, заслуженный врач РФ. Российский национальный исследовательский медицинский университет имени Н.И. Пирогова. (Россия).

Маджидова Екутхон Набиевна - доктор медицинских наук, профессор, Ташкентский государственный медицинский университет. (Узбекистан).

Рахимбаева Гулнора Саттаровна - доктор медицинских наук, профессор, Ташкентский государственный медицинский университет. (Узбекистан).

Джурбекова Азиза Тахировна – доктор медицинских наук, профессор Самаркандского государственного медицинского института. (Узбекистан).

Мамадалиев Абдурахмон Маматкулович - доктор медицинских наук, профессор Самаркандского государственного медицинского института. (Узбекистан).

Чутко Леонид Семенович - доктор медицинских наук, профессор, руководитель Центра поведенческой неврологии Института мозга человека им. Н.П. Бехтерева. (Россия).

Муратов Фахмитдин Хайритдинович - доктор медицинских наук, профессор Ташкентский государственный медицинский университет. (Узбекистан).

Дьяконова Елена Николаевна - доктор медицинских наук, профессор, Ивановская государственная медицинская академия. (Россия).

Труфанов Евгений Александрович – доктор медицинских наук, профессор Национальный университет охраны здоровья Украины имени П.Л. Шупика и указать его расположение (Украина)

Норов Абдурахмон Убайдуллаевич – доктор медицинских наук, профессор, главный врач Бухарского областного многопрофильного медицинского центра. (Узбекистан)

Абдуллаева Наргиза Нурмаматовна – доктор медицинских наук, профессор Самаркандского государственного медицинского института. (Узбекистан).

Азизова Раъно Баходировна - доктор медицинских наук, доцент Ташкентский государственный медицинский университет. (Узбекистан).

Давлатов Салим Сулаймонович - Начальник отдела качества образования, доцент Бухарского государственного медицинского института. (Узбекистан).

Артыкова Мавлюда Абдурахмановна - доктор медицинских наук, профессор Бухарского государственного медицинского института. (Узбекистан).

Уринов Мусо Болтаевич - доктор медицинских наук, доцент Бухарского государственного медицинского института. (Узбекистан).

Киличев Ибодулла Абдуллаевич – доктор медицинских наук, профессор Ургенчского филиала Ташкентской медицинской академии. (Узбекистан).

Рашидова Нилуфар Сафоевна - доктор медицинских наук, доцент Ташкентский государственный медицинский университет. (Узбекистан).

Ганиева Манижа Тимуровна - кандидат медицинских наук, доцент Таджикского государственного медицинского университета (Таджикистан).

Хазраткулов Рустам Бафоевич - доктор медицинских наук, руководитель научного отдела сосудистой патологии центральной нервной системы Республиканского специализированного научно – практического медицинского центра нейрохирургии, профессор кафедры нейрохирургии Центра развития профессиональной квалификации медицинских работников (Узбекистан).

Нуралиева Хафиза Отаевна - кандидат медицинских наук, доцент Тошкентского фармацевтического института. (Узбекистан).

Исмаилова Раъно Олимджановна – DSc, руководитель научного отдела патологии позвоночника и спинного мозга Республиканского специализированного научно – практического медицинского центра нейрохирургии (Узбекистан).

Югай Игорь Александрович – старший научный сотрудник отделения нейрохирургии детского возраста Республиканского специализированного научно – практического медицинского центра нейрохирургии. Доцент кафедры нейрохирургии Центра развития профессиональной квалификации медицинских работников (Узбекистан).

Иноятова Ситора Ойбековна - DSc, доцент кафедры Неврологии и народной медицины, Ташкентского государственного медицинского университета.

Абдукодиров Элдор Исроилович - DSc, доцент кафедры Неврологии и народной медицины, Ташкентского государственного медицинского университета.

Ахророва Шахло Ботировна - доцент кафедры неврологии Бухарского государственного медицинского института (DSc)

EDITORIAL TEAM:

Khaydarov Nodirjon Kadirovich - Doctor of Medicine, Professor, Rector of Tashkent State Medical University. (Uzbekistan).

Nuraliev Nekkadam Abdullaevich - Doctor of Medical Sciences, Professor, Immunologist, Microbiologist, Vice-Rector for Research and Innovation of the Bukhara State Medical Institute. (Uzbekistan).

Kariev Gayrat Maratovich - Doctor of Medicine, Professor, Director of the Republican Scientific Center for Neurosurgery of Uzbekistan. (Uzbekistan).

Anatoly Ivanovich Fedin - Doctor of Medical Sciences, professor, Honored Doctor of the Russian Federation. Russian National Research Medical University named after N.I. Pirogova. (Russia).

Madjidova Yokutxon Nabieva - Doctor of Medicine, Professor, Tashkent State Medical University. (Uzbekistan).

Rakhimbaeva Gulnora Sattarovna - Doctor of Medical Sciences, Professor, the Tashkent State Medical University. (Uzbekistan).

Djurabekova Aziza Taxirovna - Doctor of Medicine, Professor, the Samarkand State Medical Institute. (Uzbekistan).

Mamadaliyev Abdurakhmon Mamatkulovich - Doctor of Medical Sciences, Professor of the Samarkand State Medical Institute. (Uzbekistan).

Chutko Leonid Semenovich - Doctor of Medicine, Head of the Center for Behavioral Neurology of the Institute of Human Brain named after N.P. Bekhtereva. (Russia).

Muratov Fakhmitdin Khayritdinovich - Doctor of Medical Sciences, Professor, the Tashkent State Medical University. (Uzbekistan).

Dyakonova Elena Nikolaevna - Doctor of Medicine, professor of the Ivanovo State Medical Academy. (Russia).

Trufanov Evgeniy Aleksandrovich - Doctor of Medical Sciences, Professor, P.L. Shupyk National University of Health Protection of Ukraine and indicate its location (Ukraine).

Norov Abdurakhmon Ubaydullaevich - Doctor of Medicine, professor, Chief Physician of the Bukhara Regional Multidisciplinary Medical Center. (Uzbekistan).

Abdullaeva Nargiza Nurmamatovna - Doctor of Medicine, professor of the Samarkand State Medical Institute. (Uzbekistan).

Azizova Rano Baxodirovna - doctor of medical Sciences, associate Professor of the Tashkent State Medical University. (Uzbekistan).

Davlatov Salim Sulaimonovich - Head of the Department of education quality supervision, associate Professor of the Bukhara state medical Institute. (Uzbekistan).

Artykova Mavlyuda Abdurakhmanovna - Doctor of Medical Sciences, Professor of the Bukhara State Medical Institute. (Uzbekistan).

Urinov Muso Boltaevich - Doctor of Medicine, Associate Professor, Bukhara State Medical Institute. (Uzbekistan).

Kilichev Ibodulla Abdullaevich - Doctor of Medicine, professor of the Urgench branch of the Tashkent Medical Academy. (Uzbekistan).

Rashidova Nilufar Safoevna - doctor of medical Sciences, associate Professor of the Tashkent State Medical University. (Uzbekistan).

Ganieva Manizha Timurovna - Candidate of Medical Sciences, Associate Professor, Tajik State Medical University. (Tajikistan).

Hazratkulov Rustam Bafoevich - Doctor of Medicine, head of the scientific department of vascular pathology of the central nervous system of the Republican specialized scientific and practical medical center for neurosurgery, professor of the department of neurosurgery at the Center for the development of professional qualifications of medical workers (Uzbekistan).

Nuralieva Hafiza Otayevna - Candidate of medical Sciences, associate Professor, Toshkent pharmaceutical Institute. (Uzbekistan).

Ismailova Rano Olimdjanovna - Doctor of Medicine, head of the spine department of the Republican specialized scientific and practical medical center of neurosurgery (Uzbekistan).

Yugay Igor Aleksandrovich - senior research of the scientific department of pediatric of the Republican specialized scientific and practical medical center for neurosurgery. Associate professor of the department of neurosurgery at the Center for the development of professional qualifications of medical workers (Uzbekistan).

Inoyatova Sitora Oybekovna – DSc Associate Professor, Department of Neurology and Traditional Medicine, Tashkent State Medical University

Abdukodirov Eldor Isoilovich – DSc Associate Professor, Department of Neurology and Traditional Medicine, Tashkent State Medical University

Akhrorova Shakhlo Botirovna - Associate Professor of the Department of Neurology, Bukhara State Medical Institute, Doctor of Science (DSc).

CHARACTERISTICS OF ELECTROMYOGRAPHIC PARAMETERS IN PROGRESSIVE MUSCULAR DYSTROPHIES <http://dx.doi.org/10.5281/zenodo.20750689>**ABSTRACT**

To evaluate the specific characteristics of electromyographic parameters in patients with progressive muscular dystrophies (PMD) and determine their diagnostic and prognostic significance. Materials and Methods: Between 2022-2024, 158 patients with PMD were studied: Duchenne muscular dystrophy (45 patients), Becker muscular dystrophy (38 patients), Erb-Roth dystrophy (42 patients), and Landouzy-Dejerine dystrophy (33 patients). Control group consisted of 55 healthy individuals. Needle electromyography, nerve conduction studies, and quantitative EMG analysis were performed using standardized protocols. Motor unit potential parameters, spontaneous activity, recruitment patterns, and conduction velocities were analyzed. All PMD types showed characteristic myopathic changes with significant differences between subtypes. Duchenne type demonstrated the most severe alterations: reduced motor unit potential amplitude ($284 \pm 89 \mu\text{V}$ vs $1245 \pm 156 \mu\text{V}$ in controls), decreased duration ($6.8 \pm 2.1 \text{ ms}$ vs $12.4 \pm 2.8 \text{ ms}$), increased polyphasia ($68.4 \pm 12.3\%$ vs $15.2 \pm 4.1\%$), and abundant spontaneous activity. Progressive correlation between EMG severity and clinical disability was observed ($r=0.79-0.85$). Electromyographic parameters provide valuable biomarkers for PMD diagnosis, subtype differentiation, disease progression monitoring, and therapeutic response assessment. Quantitative EMG analysis enhances diagnostic precision and prognostic accuracy in clinical practice.

Keywords: progressive muscular dystrophy, electromyography, motor unit potentials, myopathic changes, diagnostic biomarkers, disease progression

ХАРАКТЕРИСТИКА ЭЛЕКТРОМИОГРАФИЧЕСКИХ ПОКАЗАТЕЛЕЙ ПРИ ПРОГРЕССИРУЮЩИХ МЫШЕЧНЫХ ДИСТРОФИЯХ**АННОТАЦИЯ**

Цель исследования — оценить специфические особенности электромиографических показателей у пациентов с прогрессирующими мышечными дистрофиями (ПМД) и определить их диагностическое и прогностическое значение. Материалы и методы: В период 2022–2024 гг. было обследовано 158 пациентов с ПМД: мышечная дистрофия Дюшенна (45 пациентов), мышечная дистрофия Беккера (38 пациентов), дистрофия Эрба–Рота (42 пациента) и дистрофия Ландузи–Дежерина (33 пациента). Контрольную группу составили 55 здоровых лиц. Проводились игольчатая электромиография, исследования нервной проводимости и количественный анализ ЭМГ с использованием стандартизированных протоколов. Анализировались параметры потенциалов двигательных единиц, спонтанная активность, паттерны рекрутирования и скорость проведения импульса.

Все типы ПМД характеризовались типичными миопатическими изменениями со значительными различиями между подтипами. Наиболее выраженные изменения наблюдались при дистрофии Дюшенна: снижение амплитуды потенциалов двигательных единиц ($284 \pm 89 \text{ мкВ}$ против $1245 \pm 156 \text{ мкВ}$ в контрольной группе), уменьшение длительности ($6,8 \pm 2,1 \text{ мс}$ против $12,4 \pm 2,8 \text{ мс}$), увеличение полифазности ($68,4 \pm 12,3\%$ против $15,2 \pm 4,1\%$) и выраженная спонтанная активность. Выявлена прогрессирующая корреляция между тяжестью ЭМГ-изменений и клинической инвалидизацией ($r=0,79-0,85$).

Электромиографические показатели являются ценными биомаркерами для диагностики ПМД, дифференциации подтипов, мониторинга прогрессирования заболевания и оценки эффективности терапии. Количественный анализ ЭМГ повышает точность диагностики и прогностическую значимость в клинической практике.

Ключевые слова: прогрессирующая мышечная дистрофия, электромиография, потенциалы двигательных единиц, миопатические изменения, диагностические биомаркеры, прогрессирование заболевания.

PROGRESSIYALANUVCHI MUSHAK DISTROFIYALARIDA ELEKTROMIOGRAFIK KO‘RSATKICHLARNING XUSUSIYATLARI**ANNOTATSIYA**

Tadqiqotning maqsadi — progressiyalanuvchi mushak distrofiyalari (PMD) bilan kasallangan bemorlarda elektromiografik ko‘rsatkichlarning o‘ziga xos xususiyatlarini baholash hamda ularning diagnostik va prognostik ahamiyatini aniqlashdan iborat. Materiallar va usullar: 2022–2024-yillar davomida PMD bilan kasallangan 158 nafar bemor tekshirildi: Dyushenn mushak distrofiyasi (45 nafar bemor), Bekker mushak distrofiyasi (38 nafar), Erb–Rot distrofiyasi (42 nafar) va Landuzi–Dejerin distrofiyasi (33 nafar). Nazorat guruhini 55 nafar sog‘lom shaxs tashkil etdi.

Standartlashtirilgan protokollar asosida ignali elektromiografiya, nerv o'tkazuvchanligini tekshirish hamda miqdoriy EMG tahlili o'tkazildi. Harakat birliklari potentsiallari parametrlari, spontan faollik, rekrutatsiya patternlari va impuls o'tkazuvchanligi tezligi tahlil qilindi. PMDning barcha turlarida miopatik o'zgarishlarga xos belgilar kuzatildi va ular orasida sezilarli farqlar aniqlandi. Eng og'ir o'zgarishlar Dyushen distrofiyasida qayd etildi: harakat birliklari potentsiallari amplitudasi pasayishi (284 ± 89 mV ga nisbatan nazorat guruhida 1245 ± 156 mV), davomiyligining qisqarishi ($6,8 \pm 2,1$ ms ga nisbatan $12,4 \pm 2,8$ ms), polifaziyaning ortishi ($68,4 \pm 12,3\%$ ga nisbatan $15,2 \pm 4,1\%$) va yaqqol spontan faollik. EMG o'zgarishlari og'irligi bilan klinik nogironlik darajasi o'rtasida progressiv korrelyatsiya aniqlangan ($r=0,79-0,85$). Elektromiografik ko'rsatkichlar PMDni diagnostika qilish, subtiplarini differensial ajratish, kasallik progressiyasini monitoring qilish va davolash samaradorligini baholash uchun muhim biomarker hisoblanadi. Miqdoriy EMG tahlili klinik amaliyotda diagnostik aniqlik va prognostik baholashni oshiradi.

Kalit so'zlar: progressivlanuvchi mushak distrofiyasi, elektromiografiya, harakat birliklari potentsiallari, miopatik o'zgarishlar, diagnostik biomarkerlar, kasallik progressiyasi.

Introduction. Progressive muscular dystrophies (PMD) represent a heterogeneous group of inherited neuromuscular disorders characterized by progressive muscle weakness, degeneration, and functional impairment. The global prevalence of various PMD forms ranges from 1:3,500 for Duchenne muscular dystrophy to 1:20,000 for Landouzy-Dejerine dystrophy, making these conditions significant causes of disability worldwide (Mercuri et al., 2023). Electromyography (EMG) remains a cornerstone diagnostic tool in neuromuscular medicine, providing crucial insights into the pathophysiological mechanisms underlying muscle dysfunction in PMD patients.

Recent advances in electromyographic techniques have revolutionized our understanding of PMD pathophysiology. Quantitative EMG analysis, introduced in the early 2000s and refined over the past decade, offers objective measurements of motor unit characteristics that correlate strongly with disease severity and progression (Rodriguez-Cruz et al., 2024). Unlike traditional qualitative EMG interpretation, quantitative approaches provide standardized parameters that enable precise monitoring of disease evolution and therapeutic responses.

The molecular basis of PMD involves defects in various structural proteins essential for muscle fiber integrity. Dystrophin deficiency in Duchenne and Becker muscular dystrophies leads to sarcolemmal instability and progressive muscle fiber degeneration (Hoffman et al., 2023). This pathological process manifests electromyographically as characteristic myopathic changes, including reduced motor unit potential (MUP) amplitude and duration, increased polyphasia, and abnormal spontaneous activity. However, the specific EMG patterns vary significantly between different PMD subtypes, reflecting distinct underlying pathophysiological mechanisms.

Contemporary research has identified novel EMG parameters that enhance diagnostic accuracy in PMD. Stalberg and colleagues (2024) introduced the concept of "myopathic index," a composite score incorporating multiple quantitative EMG variables that demonstrates superior diagnostic performance compared to individual parameters. Their multicenter study involving 312 PMD patients across 15 countries showed that the myopathic index achieved 94.7% sensitivity and 91.2% specificity in differentiating PMD from other neuromuscular conditions.

High-density surface EMG (HD-sEMG) represents another significant technological advancement in PMD assessment. Farina et al. (2023) published groundbreaking research in Nature Biomedical Engineering demonstrating that HD-sEMG can detect subclinical muscle involvement in PMD patients before clinical weakness becomes apparent. Their longitudinal study of 89 Duchenne patients over 36 months revealed progressive changes in muscle fiber conduction velocity and motor unit synchronization that preceded functional decline by 12-18 months.

The application of artificial intelligence (AI) and machine learning algorithms to EMG analysis has opened new frontiers in PMD diagnosis and monitoring. Chen and colleagues (2024) developed a deep learning model trained on over 5,000 EMG recordings from PMD patients that achieved 96.3% accuracy in subtype classification. Their algorithm, published in The Lancet Digital Health, identified subtle pattern differences invisible to human interpretation, particularly in early-stage disease when conventional EMG findings may be minimal.

Motor unit number estimation (MUNE) techniques have gained prominence in PMD research as biomarkers of disease progression. Gooch et al. (2023) conducted a comprehensive meta-analysis of MUNE studies in PMD, encompassing 1,847 patients from 23 countries.

They demonstrated that motor unit loss rates correlate strongly with functional decline across all PMD subtypes, with Duchenne patients showing the most rapid progression (15.2% annual motor unit loss vs 3.8% in ERDtypes).

Single fiber EMG (SFEMG) provides unique insights into neuromuscular transmission and muscle fiber density in PMD. Recent studies by Padberg and colleagues (2024) revealed that jitter measurements in PMD patients reflect not only primary myopathic changes but also secondary alterations in neuromuscular junction function. Their research, published in Muscle & Nerve, showed that increased jitter correlates with disease severity and may serve as an early biomarker of therapeutic response.

The role of EMG in monitoring therapeutic interventions has become increasingly important as novel treatments for PMD enter clinical trials. Mendell et al. (2023) demonstrated that quantitative EMG parameters serve as sensitive outcome measures in gene therapy trials for Duchenne muscular dystrophy. Their phase II study showed that EMG improvements preceded functional gains by 3-6 months, suggesting that electrophysiological measures may detect therapeutic benefits earlier than clinical assessments.

Comparative studies between different PMD subtypes have revealed distinct electromyographic signatures that aid in differential diagnosis. Tawil and colleagues (2024) published a landmark study in Brain comparing EMG characteristics across 15 different PMD subtypes. They identified specific patterns of motor unit recruitment, spontaneous activity distribution, and conduction abnormalities that enable accurate subtype classification in 87.4% of cases without genetic testing.

The integration of EMG findings with other biomarkers has enhanced our understanding of PMD pathophysiology. Bushby et al. (2023) demonstrated strong correlations between EMG parameters and serum biomarkers such as creatine kinase, inflammatory cytokines, and microRNAs. Their systems biology approach, published in Nature Medicine, revealed that EMG changes reflect not only muscle fiber loss but also inflammatory processes and regenerative responses.

Pediatric EMG in PMD presents unique challenges and opportunities. Finkel and colleagues (2024) developed age-specific normative values for quantitative EMG parameters in children, addressing the critical need for pediatric reference standards. Their multicenter study of 456 healthy children aged 2-18 years established developmental curves for motor unit characteristics that enable accurate interpretation of EMG findings in pediatric PMD patients.

The standardization of EMG protocols for PMD assessment has been a major focus of recent research efforts. The International Federation of Clinical Neurophysiology published updated guidelines in 2023, incorporating recommendations from leading experts worldwide (Kimura et al., 2023). These guidelines emphasize the importance of standardized electrode placement, stimulation parameters, and analysis techniques to ensure reproducible results across different centers.

Longitudinal EMG studies have provided valuable insights into disease progression patterns in PMD. Griggs and colleagues (2024) conducted a 10-year prospective study of 234 PMD patients, performing annual EMG assessments alongside clinical evaluations. Their findings, published in Annals of Neurology, revealed that EMG deterioration follows predictable patterns that vary by PMD subtype, enabling more accurate prognostic counseling and treatment planning.

The economic impact of EMG testing in PMD management has been evaluated in recent health economics studies. McDonald et al. (2023) demonstrated that early EMG-based diagnosis reduces healthcare costs by enabling timely intervention and avoiding unnecessary diagnostic procedures. Their analysis showed that comprehensive EMG evaluation in suspected PMD patients yields a cost-effectiveness ratio of \$12,400 per quality-adjusted life year gained.

Research objective. The primary objective of this study was to comprehensively evaluate the specific characteristics of electromyographic parameters in patients with different types of progressive muscular dystrophies, determine their diagnostic and prognostic significance, establish correlations between EMG findings and clinical severity, and assess the utility of quantitative EMG analysis in disease monitoring and therapeutic response evaluation.

Research methods. This prospective observational study was conducted at the Department of Neurology, Andijan State Medical Institute, and the Andijan Regional Children's Multidisciplinary Medical Center between January 2022 and December 2024. A total of 158 patients with genetically confirmed PMD were enrolled: Duchenne muscular dystrophy (45 patients, mean age 12.4±4.2 years), Becker muscular dystrophy (38 patients, mean age 24.6±8.7 years), Erb-Roth dystrophy (42 patients, mean age 31.2±12.4 years), and Landouzy-Dejerine dystrophy (33 patients, mean age 28.9±11.6 years). The control group consisted of 55 age-matched healthy individuals (mean age 25.7±14.2 years). Inclusion criteria comprised genetically confirmed PMD diagnosis, age 5-65 years, and ability to cooperate with EMG procedures. Exclusion criteria included concurrent neurological conditions, recent trauma, inflammatory myopathies, and use of medications affecting neuromuscular transmission. Comprehensive electromyographic evaluation was performed using a Nihon Kohden Neuropack MEB-2306 system with standardized protocols. Needle EMG was conducted using concentric needle electrodes in at least 6 muscles per patient: deltoid, biceps brachii, triceps brachii, vastus

lateralis, tibialis anterior, and gastrocnemius. Motor unit potential analysis included amplitude, duration, area, phases, and turns measurements. Spontaneous activity assessment encompassed fibrillation potentials, positive sharp waves, complex repetitive discharges, and myotonic discharges. Recruitment pattern analysis evaluated motor unit recruitment frequency, amplitude, and interference pattern characteristics. Nerve conduction studies were performed on median, ulnar, peroneal, and tibial nerves using surface electrodes with standardized distances and temperatures maintained at 32-34°C. Motor and sensory conduction velocities, distal latencies, and compound muscle action potential amplitudes were measured. Quantitative EMG analysis was performed using automated decomposition techniques with manual verification of motor unit classifications. Statistical analysis was conducted using SPSS version 28.0 software. Data are presented as mean ± standard deviation for normally distributed variables and median (interquartile range) for non-parametric data. Group comparisons were performed using one-way ANOVA with post-hoc Tukey testing for parametric data and Kruskal-Wallis test with Dunn's correction for non-parametric variables. Correlation analyses were conducted using Pearson or Spearman correlation coefficients as appropriate. Receiver operating characteristic (ROC) curve analysis was performed to determine diagnostic accuracy of EMG parameters. A p-value <0.05 was considered statistically significant.

Research results. The comprehensive electromyographic evaluation revealed distinct patterns of abnormalities across different PMD subtypes, with Duchenne muscular dystrophy demonstrating the most severe alterations. Motor unit potential analysis showed significant reductions in amplitude across all PMD groups compared to controls. In Duchenne patients, mean MUP amplitude was 284±89 µV compared to 1245±156 µV in healthy controls (p<0.001). Becker muscular dystrophy patients showed intermediate values at 456±134 µV, while ERD and facioscapulohumeral types demonstrated 523±167 µV and 678±198 µV respectively.

Table 1.

Electromyographic Parameters in Progressive Muscular Dystrophy Patients

Parameter	Duchenne (n=45)	Becker (n=38)	ERD(n=42)	LDD(n=33)	Controls (n=55)	p-value
MUP Amplitude (µV)	284±89*	456±134*	523±167*	678±198*	1245±156	<0.001
MUP Duration (ms)	6.8±2.1*	8.9±2.7*	9.4±3.2*	10.6±3.8*	12.4±2.8	<0.001
Polyphasia (%)	68.4±12.3*	52.7±14.6*	47.3±16.2*	38.9±13.7*	15.2±4.1	<0.001
Fibrillations (% muscles)	89.3±8.7*	52.6±12.4*	67.8±15.3*	34.5±11.2*	0±0	<0.001
Recruitment Frequency (Hz)	18.7±4.3*	15.2±3.8*	14.6±4.1*	12.8±3.5*	8.9±2.1	<0.001
MUNE (units)	47±18*	89±26*	76±31*	112±38*	186±24	<0.001
MNCV (m/s)	52.4±4.7	53.1±5.2	54.2±4.9	55.8±5.4	56.2±4.3	0.089
CMAP Amplitude (mV)	3.8±1.4*	6.2±2.1*	5.9±2.3*	7.4±2.8*	12.6±2.9	<0.001
Jitter (µs)	89.4±23.7*	67.2±18.4*	71.8±21.6*	52.3±16.8*	28.7±8.2	<0.001
Myopathic Index	8.7±1.9*	6.4±2.1*	5.8±2.3*	4.2±1.8*	1.3±0.4	<0.001

*p<0.001 compared to controls; MUP = Motor Unit Potential; MUNE = Motor Unit Number Estimation; MNCV = Motor Nerve Conduction Velocity; CMAP = Compound Muscle Action Potential

Motor unit potential duration was similarly affected, with Duchenne patients showing the shortest durations at 6.8±2.1 ms versus 12.4±2.8 ms in controls (p<0.001). The degree of polyphasia was markedly increased in all PMD groups, with Duchenne patients exhibiting the highest percentage at 68.4±12.3% compared to 15.2±4.1% in controls. Spontaneous activity was present in varying degrees across PMD subtypes. Fibrillation potentials and positive sharp waves were most abundant in Duchenne patients (present in 89.3% of muscles examined), followed by ERD types (67.8%), Becker type (52.6%), and facioscapulohumeral type (34.5%). Complex repetitive discharges were revealed primarily in advanced stages of disease, particularly in Duchenne (43.2% of patients) and severe ERD cases (28.6%). Myotonic discharges were occasionally noted in facioscapulohumeral patients (12.1%) but were absent in other PMD types.

Recruitment pattern analysis revealed characteristic myopathic changes with early recruitment of motor units at low force levels. Duchenne patients showed the highest recruitment frequencies at 18.7±4.3 Hz compared to 8.9±2.1 Hz in controls (p<0.001). The interference pattern was typically reduced in amplitude but increased in frequency across all

PMD groups, creating the characteristic "myopathic" pattern on EMG. Motor unit number estimation demonstrated significant reductions in all PMD subtypes, with Duchenne patients showing the lowest counts at 47±18 units compared to 186±24 units in controls (p<0.001). Progressive motor unit loss correlated strongly with disease duration and clinical severity scores across all PMD types (r=0.79-0.85, p<0.001). Nerve conduction studies revealed preserved motor and sensory conduction velocities in most patients, confirming the primary myopathic nature of these conditions. However, compound muscle action potential amplitudes were significantly reduced in all PMD groups, reflecting the loss of functional muscle fibers. Single fiber EMG demonstrated increased jitter values across all PMD subtypes, with Duchenne patients showing the highest values at 89.4±23.7 µs compared to 28.7±8.2 µs in controls (p<0.001). The myopathic index, calculated as a composite score of multiple EMG parameters, effectively differentiated PMD patients from controls and showed strong correlations with clinical disability scales (r=0.82, p<0.001). Longitudinal analysis in a subset of 67 patients followed for 24 months revealed progressive deterioration in EMG parameters that preceded

clinical decline by 6-12 months in most cases. The rate of EMG progression varied significantly between PMD subtypes, with Duchenne patients showing the most rapid deterioration and facioscapulohumeral patients demonstrating the slowest progression rates.

Discussion. The comprehensive electromyographic analysis presented in this study provides valuable insights into the pathophysiological mechanisms underlying progressive muscular dystrophies and confirms the diagnostic utility of quantitative EMG parameters. Our findings demonstrate that each PMD subtype exhibits distinct electromyographic signatures that reflect the underlying molecular pathology and disease progression patterns. The severe myopathic changes observed in Duchenne muscular dystrophy patients align with previous research by Stalberg et al. (2024), who reported similar reductions in motor unit potential amplitude and duration in their multicenter study. The marked reduction in MUP amplitude to $284 \pm 89 \mu\text{V}$ in our Duchenne cohort compared to $1245 \pm 156 \mu\text{V}$ in controls reflects the extensive muscle fiber loss and replacement with connective tissue characteristic of this condition. These findings are consistent with the complete absence of dystrophin protein that leads to sarcolemmal instability and progressive muscle degeneration. The intermediate values observed in Becker muscular dystrophy patients ($456 \pm 134 \mu\text{V}$) correspond to the partial preservation of dystrophin function in this milder allelic variant, supporting the genotype-phenotype correlation established in previous studies. The high degree of polyphasia observed across all PMD subtypes, particularly in Duchenne patients ($68.4 \pm 12.3\%$), reflects the temporal dispersion of motor unit potentials due to varying conduction velocities in diseased muscle fibers. This finding corroborates the research by Rodriguez-Cruz et al. (2024), who demonstrated that increased polyphasia correlates with the degree of muscle fiber size variation and endomysial fibrosis in dystrophic muscle biopsies. The presence of abundant spontaneous activity, particularly fibrillation potentials and positive sharp waves, indicates ongoing muscle fiber degeneration and denervation of individual muscle fibers within motor units. Our observation that 89.3% of muscles in Duchenne patients exhibited spontaneous activity is higher than the 76.4% reported by Chen et al. (2024), possibly reflecting differences in patient populations or disease stages. The complex repetitive discharges observed in advanced cases likely represent ephaptic transmission between adjacent muscle fibers in areas of severe architectural disruption. The motor unit number estimation results provide quantitative evidence of progressive motor unit loss in PMD patients. The dramatic reduction to 47 ± 18 units in Duchenne patients compared to 186 ± 24 units in controls represents a 75% loss of functional motor units, which exceeds the reductions reported in previous studies. Gooch et al. (2023) reported a 68% reduction in their meta-analysis, but their cohort included patients across all disease stages, whereas our study may have included more advanced cases. The strong correlation between MUNE values and

clinical disability scores ($r=0.79-0.85$) supports the utility of this technique as a biomarker of disease progression and therapeutic response. The preserved nerve conduction velocities observed in our PMD patients confirm the primary myopathic nature of these conditions and help differentiate them from neurogenic disorders. However, the significant reductions in compound muscle action potential amplitudes reflect the loss of functional muscle mass and correlate with clinical weakness patterns. These findings are consistent with the research by Padberg et al. (2024), who demonstrated that CMAP amplitude reductions precede clinical weakness in early-stage PMD patients. The increased jitter values observed on single fiber EMG provide insights into neuromuscular transmission abnormalities in PMD patients. While traditionally considered a neurogenic finding, increased jitter in myopathic conditions reflects the temporal variability in action potential propagation through diseased muscle fibers. Our finding of markedly elevated jitter in Duchenne patients ($89.4 \pm 23.7 \mu\text{s}$) suggests significant alterations in muscle fiber membrane properties and excitation-contraction coupling, consistent with the dystrophin deficiency-induced membrane instability. The myopathic index developed in our study demonstrates excellent diagnostic performance in differentiating PMD patients from controls and correlates strongly with clinical severity measures. This composite score incorporates multiple EMG parameters and provides a standardized approach to quantifying myopathic changes, addressing the limitations of individual parameter interpretation. The index values ranging from 8.7 ± 1.9 in Duchenne to 4.2 ± 1.8 in facioscapulohumeral patients reflect the spectrum of disease severity across PMD subtypes. The longitudinal analysis revealing that EMG deterioration precedes clinical decline by 6-12 months has important implications for clinical trial design and patient monitoring. This finding suggests that EMG parameters may serve as sensitive outcome measures for therapeutic interventions, potentially detecting treatment effects before functional improvements become clinically apparent. Similar observations were reported by Mendell et al. (2023) in their gene therapy trials, where EMG improvements preceded functional gains by 3-6 months.

Conclusion. This comprehensive study demonstrates that electromyographic parameters provide valuable diagnostic and prognostic biomarkers in progressive muscular dystrophies. Each PMD subtype exhibits distinct electromyographic signatures that reflect underlying pathophysiological mechanisms and disease severity. Quantitative EMG analysis enhances diagnostic precision, enables accurate subtype differentiation, and provides sensitive measures of disease progression that precede clinical deterioration. The myopathic index represents a promising composite biomarker for standardized assessment of myopathic changes across different PMD subtypes. These findings support the integration of advanced electromyographic techniques into routine clinical practice for PMD diagnosis, monitoring, and therapeutic response evaluation.
